

## Typology Characterization of Farmers in Tanzania

April 5<sup>th</sup> 2016

Sara Signorelli

### Introduction

Africa RISING is testing alternative technology options with heterogeneous populations of farmers that will likely respond to the technologies differently. Creating farm typologies is one approach to design targeted interventions that adequately address the needs of different types of farmers. Notably, creating typologies can help:

- **Identify suitable farms to target innovations (ex-ante):** we assume that not all innovations are appropriate for all farms, and that structuring into groups would support the identification of technology-specific suitable farming systems.
- **Scale out innovations:** on the basis of the heterogeneity in a population we can formulate extension messages, policies and other incentive schemes to further spread the use of designed innovations.
- **Assess agro-economic effects (ex-post)** Explaining trends and farmer 'behavior' (functional characteristics, including sustainable intensification indicators) and verification of the agro-economic effects of the interventions for different farm types.

This document presents a summary of a typology study done using quantitative statistical methods (discussed below) applied to micro data from the Tanzania Africa RISING Baseline Evaluation Survey (TARBES) (conducted in 2014) and secondary data on environmental/biophysical variables from various source. The quantitative approaches have the advantage that they are reproducible and do not impose any ex-ante structure to the clustering process, while more qualitative approaches can potentially incorporate less tangible insights such as cultural patterns. Once the different farm types are identified through systematic quantitative analysis, they need to be validated with input from Africa RISING colleagues (especially working in Tanzania).

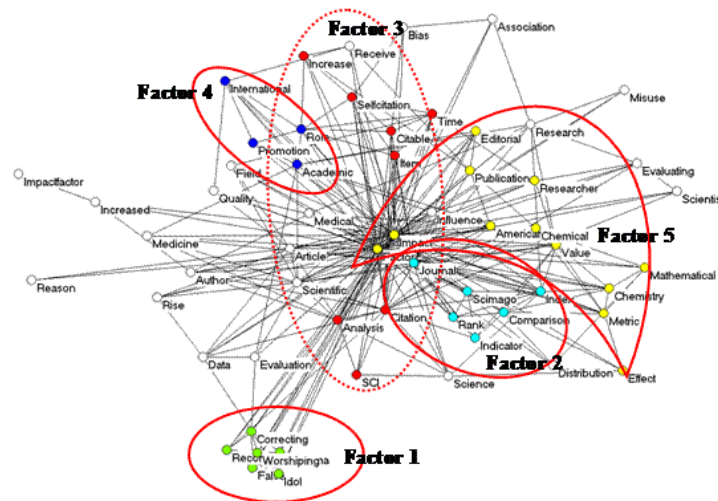

### Methodological steps

We apply a combination of factor and cluster analysis to obtain the final groups, or "types" (See Cunningham & Maloney, 1999 for an empirical application). We first use factor analysis to reduce the number of socio-economic variables to characterize the farms by selecting the most relevant ones in differentiating the sample. Factor analysis is often used to discover underlying patterns in data and its aim is to explain the largest portion of the entire dataset variation with the lowest possible number of factors. Factors are unobserved variables that summarize the correlation among several observed variables and factor analysis allows us to divide the dataset into different factors, or dimensions, and categorize each variable into one of the factors. Figure 1 shows an example of how the variables in a dataset are divided into different dimensions to explain the total variation in the data. The analysis

also allows us to rank the factors by their importance in explaining the variation in the data and to further rank each variable by its explanatory power within the factor.

**Figure 1: Example of factor analysis<sup>1</sup>**

Our factor analysis based on TARDES data involves the following main steps (see for example McDonald; 2014. Basilevsky; 2009. Mulaik; 2009 for a discussion on the methods):

1. We divide the variables in TARDES into the five domains of sustainability that have been identified within Africa RISING to gauge progress: **productivity, economic, environment, social and human**.
2. We perform separate factor analysis on each domain to select the variables that explain the largest portion of the variation in the data.
3. We use scree plots to define the number of factors to look at and, within each of the selected factors, we consider the two variables with the highest absolute values of factor loads, conditional on them being greater than 0.5 (or smaller than -0.5).
4. Finally, we obtain a parsimonious set of socio-economic variables that explain most of the variation in the data and thus are highly relevant in defining the different farm types.

The sub-set of variables obtained using steps (1) to (4) are used to perform a cluster analysis, which divides the total sample into a chosen number of clusters (Kaufman & Rousseeuw; 2009. Romesburg; 2004. Galbraith et Al.; 2002). The numbers of clusters are chosen in order to represent groups that are different enough from each other while ensuring that each group to be included has a sufficient amount of observations. There are several different methods to perform cluster analysis, some hierarchical and some non-hierarchical. We chose the hierarchical method using medians, where the distance between two clusters is calculated as the median distance between all pairs of subjects in the two clusters. The results obtained and the characteristics of each group formed are reported in the next section.

## Results

### **1. Factor analysis of productivity variables (Sustainability Domain 1)**

The scree plot of the factorization of the productivity variables (Figure 2) shows that the first three factors (represented by the first three dots at the top of the line graph) are highly relevant but that the 4<sup>th</sup> factor starts to be less important in explaining the variation (smaller vertical jump).

**Figure 2: Scree plot of productivity variables**

Table 1 shows the rotated matrix of factor loads for the three factors we have chosen, with the relevant variables highlighted ( $>0.5$  or  $<-0.5$ ). Factor 1 captures elements related to the crop diversification and intercropping practices. Factor 2 captures elements of legumes cultivation as well as the land size dedicated to intercropping. Factor 3 captures the total number of parcels and plots owned by the household as well as information on cereal cultivation. The final selection of variables for the cluster analysis include share of households doing intercropping and share of households doing intercropping with legumes for factor 1, total area intercropped and area intercropped with legumes for factor 2, and number of parcels and plots cultivated by the household for factor 3.

**Table 1: Factor loads for productivity variables**

| Variable                                    | Factor1 | Factor2 | Factor3 |
|---|---------|---------|---------|
| <i>Land size (Ha)</i>                       | -0.2532 | 0.3716  | 0.2318  |
| <i>N. parcels</i>                           | -0.0158 | 0.1534  | 0.878   |
| <i>Min distance plot</i>                    | -0.1461 | 0.0167  | -0.2057 |
| <i>Max distance plot</i>                    | -0.0079 | -0.0268 | 0.4196  |
| <i>N. trees</i>                             | 0.071   | -0.0081 | 0.1221  |
| <i>N. crops</i>                             | 0.7803  | 0.2079  | -0.1504 |
| <i>N. plots</i>                             | 0.0567  | 0.1362  | 0.9091  |
| <i>HH does intercropping</i>                | 0.796   | 0.1333  | -0.0244 |
| <i>HH does intercropping with legumes</i>   | 0.808   | 0.1524  | -0.0534 |
| <i>N. of intercropped plots</i>             | 0.5875  | 0.2909  | 0.429   |
| <i>Size intercropped land (Ha)</i>          | 0.1304  | 0.891   | 0.1383  |
| <i>Size legumes-intercropped land (Ha)</i>  | 0.1738  | 0.9074  | 0.1171  |
| <i>Ownership mixed livestock</i>            | 0.1974  | -0.076  | 0.1094  |
| <i>N. livestock types owned</i>             | 0.1775  | -0.0084 | 0.1083  |
| <i>Maize only crop</i>                      | -0.2889 | -0.0346 | -0.1067 |
| <i>Mixed crops</i>                          | 0.2889  | 0.0346  | 0.1067  |
| <i>Cultivation of cereals</i>               | 0.5929  | -0.0771 | 0.2808  |
| <i>Cultivation of vegetables</i>            | 0.0121  | -0.0251 | 0.0407  |
| <i>Cultivation of legumes</i>               | 0.6971  | 0.1344  | 0.044   |
| <i>Area cultivated with cereals (Ha)</i>    | -0.2748 | 0.4333  | 0.5274  |
| <i>Area cultivated with vegetables (Ha)</i> | 0.0367  | 0.0301  | -0.0138 |
| <i>Area cultivated with legumes (Ha)</i>    | 0.3197  | 0.5651  | 0.1995  |
| <i>Production cereals (Kg)</i>              | -0.0164 | 0.3687  | 0.5807  |
| <i>Production vegetables (Kg)</i>           | -0.0235 | -0.0015 | -0.036  |
| <i>Production legumes (Kg)</i>              | 0.1568  | 0.6399  | 0.2545  |
| <i>Yield cereals (Kg/Ha)</i>                | 0.4531  | -0.054  | 0.1257  |
| <i>Yield vegetables (Kg/Ha)</i>             | -0.0398 | -0.0231 | 0.0353  |
| <i>Yield legumes (Kg/Ha)</i>                | 0.4144  | -0.0499 | 0.0697  |
| <i>TLU small ruminants</i>                  | -0.144  | 0.1424  | 0.0159  |
| <i>TLU big ruminants</i>                    | -0.0756 | 0.1436  | 0.1568  |
| <i>TLU poultry</i>                          | 0.1087  | 0.0666  | 0.1369  |
| <i>Fertilizer used (Kg)</i>                 | 0.1771  | 0.2456  | 0.2016  |
| <i>HH does irrigation</i>                   | -0.0669 | -0.035  | 0.0746  |

Note: "N" stands for number. "HH" stands for household. "TLU" stands for Tropical Livestock Units

## 2. Factor analysis of economic variables (Sustainability Domain 2)

For the economic variables we considered, the relevant factors seem to be the first two (Figure 3).

**Figure 3: Scree plot of economic variables**

Table 2 shows that factor 1 captures quantities of crops harvest and their use while factor 2 captures labor inputs. Dwelling characteristics and non-labor inputs do not seem to account for much of the data variation. The final list of variables considered includes Kg of harvest used for seed and Kg of harvest sold (factor 1) and use of community and hired agricultural labor by the household (factor 2).

**Table 2: Factor loads for economic variables**

| Variable                                    | Factor1 | Factor2 |
|---|---------|---------|
| Fertilizer cost                             | -0.0146 | -0.0043 |
| Traditional seeds cost                      | 0.007   | 0.0553  |
| Improved seeds cost                         | 0.1772  | 0.119   |
| Pesticide cost                              | 0.1222  | 0.0992  |
| Other non-labor cost                        | 0.0315  | 0.1963  |
| Animal feed cost                            | 0.1121  | 0.0834  |
| Agricultural wage                           | 0.1831  | 0.7761  |
| HH uses community labor                     | 0.0477  | 0.9588  |
| HH uses hired labor                         | -0.0317 | 0.9577  |
| Total PD used for crops                     | 0.262   | 0.22    |
| Total harvest of grains (Kg)                | 0.9636  | 0.0676  |
| Total harvest of stover (Kg)                | 0.0217  | 0.0661  |
| Total harvest used for animal feed (Kg)     | -0.0015 | 0.0751  |
| Total harvest used for crop residual (Kg)   | -0.0067 | -0.0517 |
| Total harvest used for seeds (Kg)           | 0.9748  | -0.0053 |
| Total harvest used for gifts (Kg)           | 0.0036  | 0.1036  |
| Total harvest used for own consumption (Kg) | 0.0907  | 0.1064  |
| Total harvest used for other reasons (Kg)   | -0.0082 | 0.0227  |
| Total harvest sold (Kg)                     | 0.9779  | 0.0483  |
| Agri wealth index                           | 0.2382  | 0.0749  |
| Non-agri wealth index                       | 0.231   | 0.165   |
| Good floor material in dwelling             | 0.0945  | 0.1476  |
| Good source of drinking water               | 0.0251  | 0.0451  |
| Good toilet facility                        | 0.0155  | -0.0317 |
| Good lighting source                        | 0.0274  | 0.0842  |

Note: "HH" stands for household and "PD" refers to person-days.

### 3. Factor analysis of environment variables (Sustainability Domain 3)

For the environment domain, we identified one relevant factor concerning the problems of soil erosion and the absence of preventive measures.

**Figure 4: Scree plot of environment variables**

**Table 3: Factor loads for environment variables**

| Variable  | Factor1 |
|---|---------|
| HH uses irrigation  | 0.0584  |
| HH uses crop rotation   | 0.1213  |
| HH uses fallowing   | -0.0177 |
| HH uses alternative tillage   | 0.309   |
| HH uses manure  | 0.1049  |
| HH uses urea  | -0.0212 |
| HH experiences soil erosion   | 0.8532  |
| HH experiences soil erosion and does not takes any preventive measure | 0.8426  |
| Share of parcels with clay or loam soil                               | -0.0852 |
| Share of parcels with brown or black soil                             | -0.0448 |
| Share of parcels with incrustated soil                                | 0.1813  |
| N. of leguminous trees  | -0.0267 |
| N. of fruit trees   | -0.1301 |

#### 4. Factor analysis of social variables (Sustainability Domain 4)

Our dataset has a relatively small set of variables capturing social aspects, focusing on gender disparities. We thus chose only the first factor, which highlights the presence of females and females-only managed livestock as the main variables of interest.

**Figure 5: Scree plot of social variables**

**Table 4: Factor loads for social variables**

| Variable                                      | Factor1 |
|---|---------|
| <i>Females also responsible for plots</i>     | 0.2586  |
| <i>Females only responsible for plots</i>     | -0.007  |
| <i>Females also responsible for livestock</i> | 0.922   |
| <i>Females only responsible for livestock</i> | 0.735   |

#### 5. Factor analysis of human variables (Sustainability Domain 5)

The final sustainability domain we focus on is human capital. We select the first four factors, which capture the age composition of household members, including the prevalence of younger age groups from 0 to 29 years old (factor 1) and older age groups above 45 years old (factor 2), the level of education of household members (factor 3), and the basic characteristics of the household head (factor 4). Experiencing food shortages in the 12 months preceding interview date do not appear to play a key role in differentiating the sample. We finally select young and total dependency ratio (factor 1), mean age and mean adult age in the household (factor 2), mean level of education in the household and years of education of the household head (factor 3) and indicators of whether the household head is widow or female (factor 4).

**Figure 6: Scree plot of human variables**

**Table 5: Factor loads for human variables**

| Variable                          | Factor1 | Factor2 | Factor3 | Factor4 |
|-----------------------------------|---------|---------|---------|---------|
| HH size                           | 0.4227  | -0.1801 | 0.0555  | -0.126  |
| Head is married                   | 0.1028  | -0.0287 | 0.0446  | -0.7998 |
| Head is widow                     | -0.0084 | 0.0732  | -0.0771 | 0.9123  |
| Head is single                    | -0.0535 | -0.0611 | 0.0219  | 0.0807  |
| Head is female                    | 0.0194  | -0.0058 | -0.1051 | 0.8408  |
| Head is female and single         | 0.0571  | -0.0175 | -0.0086 | 0.1131  |
| Head is male and single           | -0.1165 | -0.0638 | 0.0353  | 0.0091  |
| Head's age                        | -0.1634 | 0.7008  | -0.1236 | 0.1808  |
| Head's years of educ              | 0.0345  | -0.1141 | 0.8896  | -0.1521 |
| Head is literate                  | 0.0828  | -0.0959 | 0.7994  | -0.1997 |
| Mean years of edu.                | -0.0954 | -0.1668 | 0.9016  | 0.0323  |
| Highest years of edu.             | -0.2058 | -0.0082 | 0.7497  | 0.0588  |
| Mean age                          | -0.5321 | 0.8121  | -0.0621 | 0.0365  |
| Mean adult age                    | 0.1472  | 0.9291  | -0.1131 | -0.0212 |
| N. of males adults                | -0.3606 | -0.046  | 0.0673  | -0.1536 |
| N. of females adults              | -0.0661 | 0.0551  | 0.0291  | 0.0881  |
| children                          | 0.666   | -0.2933 | -0.0733 | -0.1577 |
| Young dep. Ratio                  | 0.9642  | -0.0892 | -0.0195 | 0.0166  |
| Old dep. Ratio                    | 0.1987  | 0.7299  | -0.205  | 0.1209  |
| Total dep. ratio                  | 0.9601  | 0.1252  | -0.0769 | 0.0501  |
| Share of 0-14 y.o.                | 0.8875  | -0.3101 | 0.0015  | -0.0819 |
| Share of 15-29 y.o.               | -0.5595 | -0.3657 | 0.0406  | 0.1289  |
| Share of 30-44 y.o.               | 0.0006  | -0.1414 | 0.0255  | -0.006  |
| Share of > 45 y.o.                | -0.358  | 0.81    | -0.0638 | -0.0404 |
| HH worries for food shortages     | 0.0633  | 0.0047  | -0.0738 | 0.0793  |
| Months experienced food shortages | 0.0903  | 0.035   | -0.0595 | 0.0428  |

## 6. Cluster analysis

The analysis summarized in the preceding section informed the selection of a list of factors that we used in the cluster analysis. These are 6 productivity variables, 4 economic variables, 2 environmental variables, 2 social variables and 8 human variables. Figure 7 shows the dendrogram illustrating how the farm households in our sample can be split into different groups (or types) based on these variables we have identified. The vertical distance between separations illustrates the distance of the different groups to each other.

**Figure 7: Dendrogram**

Considering the number of observations within each group and differentiation of characteristics between groups, we decided to create four final groups, or “types” of farmers. Tables 6a to 6e illustrate the distribution of characteristics across these types and sustainability domains discussed before. Because the clusters were defined using the variables accounting for most of the data variation, as captured by the factor analysis, most of the characteristics differ significantly across every type. Type 1 is the biggest one and includes 331 of the farmers in the sample. Type two defines 242 farmers, type 3 accounts for 149 farmers and finally type 4 is the smallest, with 58 farmers.

**Table 6a: distribution of characteristics in the economic domain**

|   | Type 1                   | Type 2                | Type 3                   | Type 4                     |
|---|--------------------------|-----------------------|--------------------------|----------------------------|
| <b>Economic Domain</b>  |                          |                       |                          |                            |
| <i>Value of fertilizer used (GHC)</i>                         | 2521.15<br>[836.09]      | 2818.87<br>[1038.45]  | 4651.01<br>[1955.15]     | 2722.76<br>[1487.98]       |
| <i>Value of traditional seeds purchased (GHC)</i>             | 3160.42***<br>[623.05]   | 6607.02<br>[1462.87]  | 12398.47***<br>[3264.18] | 15344.83**<br>[6810.44]    |
| <i>Value of improved seed purchased (GHC)</i>                 | 23135.83***<br>[2122.67] | 44942.63<br>[3169.06] | 87839.26***<br>[6626.91] | 145139.02***<br>[21441.80] |

The four types differ from each other across all of the five domains, as shown in table 6. One of the striking characteristic that stands out in differentiating them is the level of endowments, as measured by a wealth index including dwelling characteristics, size of the cultivated land and ownership of agricultural and non-agricultural assets (figure 8). We defined low-endowed households as the ones in the bottom quartile of the wealth distribution, mid-endowed households as the ones in the 2<sup>nd</sup> and 3<sup>rd</sup> quartile and highly endowed households as the ones in the top quartile of the asset distribution. Figure 8 shows in which of the endowments category fall most of the households in our typologies. More broadly, the types can be characterized as following:

#### **Type 1: Female-headed, low educated households with low levels of endowments**

- High number of female headed households, with heads less likely to be married and with low education attainments and literacy rates.
- High proportion of women with plot responsibilities but low proportion of women with livestock responsibilities.
- Very high food insecurity.
- Little asset ownership (land below 2 Ha, little livestock, low agricultural and non-agricultural wealth), and bad dwelling conditions.

- Low production and productivity of all major crops, also due to low input use (both in terms of labor inputs, which are mainly composed by family labor, and non-labor inputs).
- Most crop production devoted to own consumption.
- Little use of soil conservation practices.

#### **Type 2: Young medium-endowed households**

- Relatively small and young households with mid-levels of education.
- Low productivity and input use, even though better than type 1, and mid-levels of endowments. Low land size (below 2 Ha).
- More likely to grow vegetables than other groups.
- Little use of soil conservation practices.

#### **Type 3: Medium-endowed households growing vegetables and practicing intercropping**

- Large households with high levels of educational attainment
- More likely to do intercropping and grow vegetables than other groups. Second group most likely to grow legumes after group 4.
- Medium levels of crop production and high productivity, coupled with very large use of fertilizer and hired labor.
- Medium levels of endowments, with average land size between 2 and 3 Ha.
- Frequent use of manure but also problems of soil incrustation.

#### **Type 4: Highly endowed households breeding livestock and growing legumes**

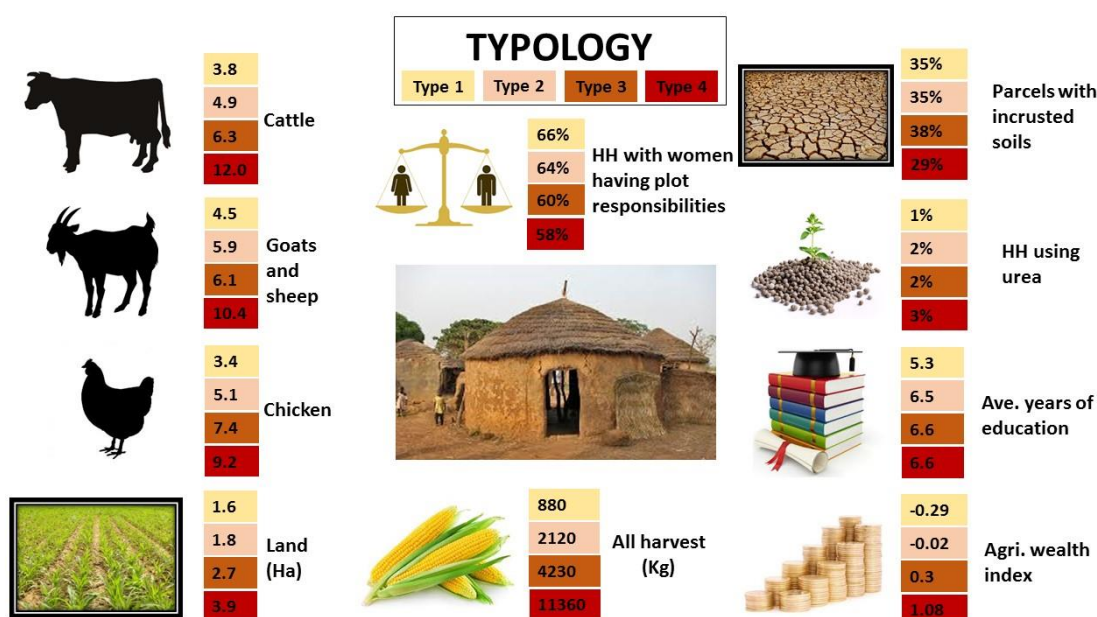

- Male headed households with high levels of literacy rates and educational attainments.
- High percentage of women with some livestock responsibilities.
- Very high levels of food security (Average months of food shortages close to zero).
- Extremely high asset ownership (large land above 3 Ha, high number of livestock types and units, high agriculture and non-agriculture index) and very good dwelling conditions.
- High production and productivity of crops with high input use. Very high share of households growing legumes (93%).
- Frequent use of crop rotation and irrigation and high share of clay or loam soils.

Table 7 summarizes the main characteristics of every type relative to each sustainability domain, providing a simplified framework for classifying farm households into a particular type. Figure 9 shows a graphic representation of the main characteristics of each type.

**Table 7: matrix of performance for each SI domain**

|  | Productivity  | Economic  | Environment   | Social (gender)   | Human  |
|--|---|---|---|---|--|
| <b>Type 1: Female-headed, low educated households with low levels of endowments</b>      | Low crop production and productivity.<br>Little livestock owned.  | Low wealth (agri and non-agri), land size below 2 Ha, low input expenditure, most harvest going to own consumption rather than sales.                             | Little use of soil conservation practices.                                  | High frequency of female responsibility for crops but opposite for livestock. | Female heads with low levels of literacy and education.<br>Very low food security.                                   |
| <b>Type 2: Young medium-endowed households</b>   | Low crop production and productivity.<br>Little livestock owned.  | Low-medium wealth (agri and non-agri), land size below 2 Ha, low input expenditure, same proportion of harvest going to own consumption and sales.                | Little use of soil conservation practices.                                  | Average gender equality.  | Small households with low dependency ratio.<br>Relatively low food security.   |
| <b>Type 3: Medium-endowed households growing vegetables and practicing intercropping</b> | High crop production and productivity.<br>Frequent intercropping.<br>Vegetable growers and second largest legume growers. | Medium-high wealth (agri and non-agri), high input use (especially fertilizer and hired labor), harvest going to sales twice the amount going to own consumption. | Frequent use of manure but also problems of soil incrustation.              | Average gender equality.  | Large households with married male heads and high levels of education and literacy.                                  |
| <b>Type 4: Highly endowed households breeding livestock and growing legumes</b>          | Very high crop production and productivity.<br>High livestock ownership.<br>Legume growers.                               | Very high wealth (agri and non-agri), high input use, harvest going to sales five times the amount going to own consumption.<br>Good dwelling conditions.         | Frequent use of soil conservation practices but problems with soil erosion. | High frequency of female responsibility for livestock but opposite for crops. | Very large households with married male heads and high levels of education and literacy.<br>Very high food security. |

**Figure 9: Graphic representation of types**

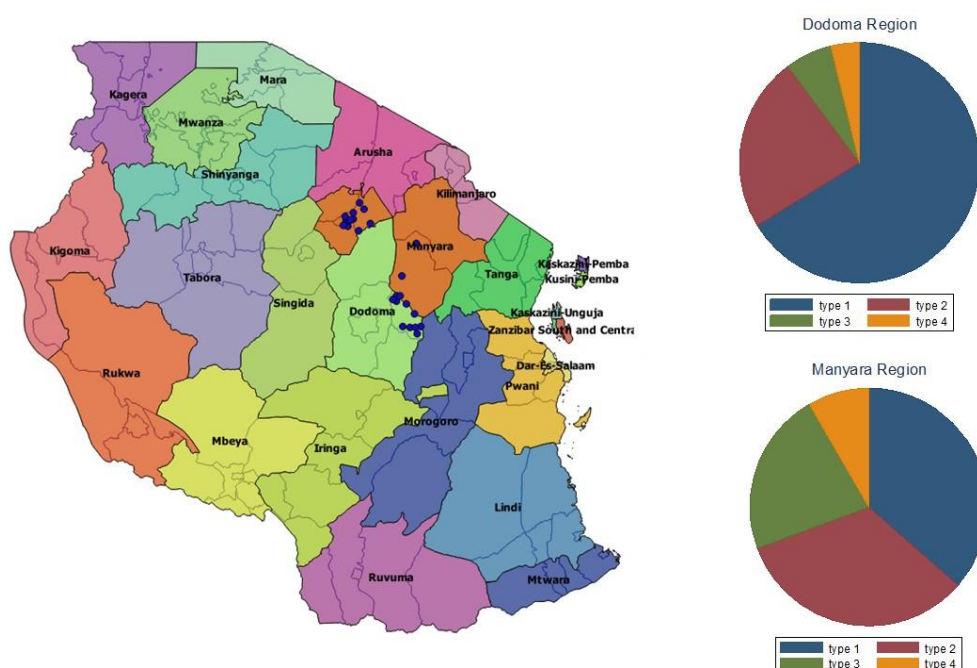

**Figure 10: Distribution of Typologies by Districts**

The differences in climatic conditions between groups are an indication of heterogeneity of typology distribution across space. Figure 10 shows the typology composition of each district in the sample. While in Kongwa there is a very high concentration of female-headed, low educated households with low levels of endowments (type 1), Kiteto and especially Babati concentrate high shares of Mid-endowed and high endowed households (type 3 and 4). Similar differences appear when we look at the regional typology distribution (Figure 11), with the Manyara region hosting a large portion of richer types while the Dodoma region mostly concentrates the poorest households (type 1). The spatial distinctions are important because they can support interventions based on the most prevalent households' typologies in the area.

**Figure 11: Distribution of Typologies by regions**

The characteristics of each household type described above can be displayed clearly with a spider plot. Figure 12 summarizes the performance of each type relative by each domain as follows:

- Type 3 and 4 are the most productive groups, while type 2 shows mid-levels of productivity and type 1 is lagging far behind.
- In terms of economic endowments, type 4 differentiate itself with a very strong performance, while the other groups are fairly close to each other at a lower level.
- In terms of human endowments, here measured by educational attainments, types 2,3 and 4 are very similar, and type 1 differentiate itself with very low levels of performance.
- Finally, type 1 and type 4, despite their wide differences in productivity, economic and human endowments, perform similarly in terms of soil conservation practices and gender equality. While type 4 might have a high respect for women and the environment because of choice, in the case of type 1 this might be a necessity driven by the scarcity of resources.

#### Recommendations:

- AR can focus on increasing the productive capacity and economic endowments for group 1 and 2 through the introduction of superior agricultural technologies. In addition, through nutrition trainings the project can improve the food insecurity of type 1 and, to a minor extent, of type 2.
- Secondly, AR can focus on sharing information about the importance of preserving soil fertility and improving gender equality. This will improve the performance of type 2 and 3 in these two domains and prevent the degradation of the scores of type 1, which may result from the improvement of his economic and productivity conditions.

The appendix includes additional graphs characterizing the obtained typologies.

**Figure 12: Typologies performance by sustainability domain**

*NOTE: The following variables are used to measure each domain: cereals yield (Productivity), asset-based wealth index (Economic), soil conservation index composed of crop rotation, alternative or minimum/zero tillage, experience of soil erosion without measures for mitigating it and share of parcels with incrustated soils (Environment); gender equality index composed by female responsibility in managing certain plots and livestock (Social), and average education in the household (Human).*
